

I build .NET backend systems where payments, access, and state must survive retries and restarts: explicit state machines, provider re-verification, durable inbox/outbox, idempotency, reconciliation, migrations, and verifiable rollback

Payment correctness
A webhook is not treated as ground truth: provider payment state is re-fetched and checked for id/status/environment/metadata/amount/currency

Recovery ownership
Durable inbox/outbox, idempotency, reconciliation, restart recovery, leases, and manual review for conflicting evidence

Release safety
Versioned releases, coordinated backup, atomic switching, health gates, and rollback to the previous release

EXPERIENCE

- 2026 — present

CompilationLabLMS — payment/backend architecture
 - Made PaymentOrder the owner of allowed state transitions, retry scheduling, and status-check leases; the webhook flow re-fetches payment state from the provider before emitting an internal event
 - Validate payment id/status/environment/metadata/amount/currency and keep malformed or unverifiable provider events separate from confirmed state
- 2026 — present

VpnMediator — state/recovery backend
 - Designed a durable payment inbox/outbox, idempotent reconciliation, and a manual-review path for conflicting provider evidence; restart recovery is covered by dedicated tests
 - Built a versioned release path with coordinated backup, atomic switching, readiness/liveness gates, and restoration of the previous release after failed startup
- 2025 — confirmed

Client development — Diploma.school
 - Implemented jQuery dropdown components, responsive mobile/desktop navigation, and UI regression fixes; the work is confirmed no later than January 2025.

PROJECTS

- CompilationLabLMS**
The architecture separates user workflows from financial invariants and supports safe migration and rollback.
- VpnMediator**
Verifiable state transitions, backup/restore, health gates, and rollback-aware deployment; the public case study excludes secrets and user data.
- UniversalToolchain / Wist2**
Implemented an end-to-end pipeline with frontend, IR, optimization passes, interpreter, and a CIL backend; current exact test manifest: 1,324/1,324.

SKILLS

- NET Backend**
C#/.NET, ASP.NET Core, REST/OpenAPI, webhooks, background services, provider integrations
- State & Data**
PostgreSQL, SQLite, transactions, explicit state machines, idempotency keys, inbox/outbox, leases
- Reliability**
provider re-verification, reconciliation, retry ownership, restart recovery, audit/manual review, backup/restore
- Operations / Platform**
Linux, Docker Compose, nginx, systemd, health gates, versioned releases, atomic switching, rollback

EDUCATION

HSE University — Software Engineering, 2026–2030

RECOGNITION

- Selected as one of the winners with UniversalToolchain / Wist2.
- Moscow / remote
